

Notes on the Boundary Conditions in Finite-Difference Algorithms

C.D. Clark III

November 8, 2024

1 Finite Difference Algorithms

1.1 Explicit Algorithms

The simplest method for solving a differential equation using the finite-difference approximation is the explicit method. The solution at the next time step is computed directly from the solution at the current time step, and can be written as

$$\mathbf{v}^{n+1} = \mathbb{P}\mathbf{v}^n + \mathbf{d} \quad (1)$$

where \mathbb{P} is the propagator, a matrix that propagates the solution forward in time, and \mathbf{d} is a source term. This matrix equation represents a system of equations, and can be written out in long form:

$$v_i^{n+1} = a_i v_{i-1}^n + b_i v_i^n + c_i v_{i+1}^n + d_i \quad (2)$$

There are two "boundaries" that have to be considered here. When $i = 0$, equation 2 refers to v_{-1} , which does not exist. At $i = N - 1$, v_N is referred to, which also does not exist. These two equations, $i = 0$ and $i = N - 1$, have to be replaced with equations that do not refer to the non-existent elements of \mathbf{v} . Actually, these two equations are just modified to only refer to actual elements of \mathbf{v} . To write the modification, a second equation relating the non-existent element of \mathbf{v} to the existing elements is required. This equation is called the "boundary condition". The boundary condition used is determined by the physics.

1.2 Implicit Algorithms

Any implicit finite difference algorithm is based on getting a matrix equation of the form

$$\mathbb{A}v = b \quad (3)$$

where, \mathbb{A} is a known matrix, b is a known vector, and v is the vector of unknowns to be solved for. For most common Finite-Difference methods, the matrix \mathbb{A} is tridiagonal, and so only three elements of v appear in each equation. The vector of knowns, b , must be calculated, and this typically involves three elements of the "current" solution. In other words, in general we usually have something like this:

$$\mathbb{A}v^{n+1} = \mathbb{C}v^n + d \quad (4)$$

where \mathbb{C} is a known matrix that operates on the current solution and gives a vector of constants, and d is a vector of constants that do not depend on the current solution.

This matrix equation represents a system of equations. One equation in this system can be written

$$a_i^L v_{i-1}^{n+1} + b_i^L v_i^{n+1} + c_i^L v_{i+1}^{n+1} = a_i^R v_{i-1}^n + b_i^R v_i^n + c_i^R v_{i+1}^n + d_i \quad (5)$$

Just as with the explicit method, there are two boundary conditions that must be handled here.

1.3 Dirichlet Boundary Conditions

The simplest boundary condition to implement is the "sink". In this case, the solution is required to be zero at the boundary, so for example if the element v_i did exist, it would be zero. In this case, the terms in 2 and 5 referring to v_{-1} and v_N can just be ignored.

1.3.1 Explicit Method

For the explicit method, the $i = 0$ difference equation becomes

$$v_0^{n+1} = b_0 v_0^n + c_0 v_1^n + d_0 \quad (6)$$

The $i = N - 1$ equation is similar,

$$v_{N-1}^{n+1} = a_{N-1} v_{N-2}^n + b_{N-1} v_{N-1}^n + d_{N-1} \quad (7)$$

However, in general, we could allow the boundary be specified as an arbitrary constant,

$$v(x_0) = f \quad (8)$$

In which case we have

$$v_{0}^{n+1} = a_0 f + b_0 v_0^n + c_0 v_1^n + d_0 \quad (9)$$

$$v_{N-1}^{n+1} = a_{N-1} v_{N-2}^n + b_{N-1} v_{N-1}^n + c f + d_{N-1} \quad (10)$$

1.3.2 Implicit Methods

The difference equations for the implicit methods are

$$a_0^L f + b_0^L v_0^{n+1} + c_0^L v_1^{n+1} = a_0^R f + b_0^R v_0^n + c_0^R v_1^n + d_0 \quad (11)$$

$$a_0^L v_{N-2}^{n+1} + b_0^L v_{N-1}^{n+1} + c_0^L f = a_0^R v_{N-2}^n + b_0^R v_{N-1}^n + c_0^R f + d_0 \quad (12)$$

Since we are solving a system of equation, any terms that are constant (don't include v_i) must be moved to the RHS of the equation. The first term on the LHS side of the $i = 0$ equation is constant, so it must be moved over to the RHS,

$$b_0^L v_0^{n+1} + c_0^L v_1^{n+1} = b_0^R v_0^n + c_0^R v_1^n + d_0 + a_0^R f - a_0^L f \quad (13)$$

If we define a d'_0 as

$$d'_0 = a_0^R f - a_0^L f \quad (14)$$

then we can write the $i = 0$ equation as

$$b_0^L v_0^{n+1} + c_0^L v_1^{n+1} = b_0^R v_0^n + c_0^R v_1^n + d_0 + d'_0 \quad (15)$$

Similarly, for the $i = N - 1$ equation, we have

$$d'_{N-1} = c_{N-1}^R f - c_{N-2}^L f \quad (16)$$

$$a_{N-1}^L v_{N-2}^{n+1} + b_{N-1}^L v_{N-1}^{n+1} = a_{N-1}^R v_{N-2}^n + b_{N-1}^R v_{N-1}^n + d_{N-1} + d'_{N-1} \quad (17)$$

1.4 Nuemann Boundary Conditions

The other type of boundary condition that can be specified involves the derivative of v (with respect to x) at the boundary. This is the type of boundary condition is required to model surfaces where the material loses energy to the environment

through convection, radiation, and evaporation. It is also the boundary condition used to model an insulator. In general, any boundary condition can be written as

$$\left. \frac{\partial v}{\partial x} \right|_{x=\text{boundary}} = f(v) \quad (18)$$

i.e., the derivative of the solution at the boundary is some function of the solution at the boundary. By finite differencing the derivative, we obtain a relationship for the non-existent element of x .

$$\frac{v_{i+1} - v_{i-1}}{x_{i+1} - x_{i-1}} = f(v_i) \quad (19)$$

So we will have

$$v_{-1} = v_1 - \Delta x f(v_0) \quad (20)$$

$$v_N = v_{N-2} + \Delta x f(v_{N-1}) \quad (21)$$

1.4.1 Explicit Method

For the explicit method, implementing the Nuemann boundary condition is straight forward, we can just substitute for v_{-1} and v_N :

$$v_0^{n+1} = a_0 (v_1^n - \Delta x f(v_0^n)) + b_0 v_0^n + c_0 v_1^n + d_0 \quad (22)$$

$$v_{N-1}^{n+1} = a_{N-1} v_{N-2}^n + b_{N-1} v_{N-1}^n + c_{N-1} (v_{N-2}^n + \Delta x f(v_{N-1}^n)) + d_{N-1} \quad (23)$$

$$(24)$$

which we rearrange to group like terms

$$v_0^{n+1} = b_0 v_0^n + (a_0 + c_0) v_1^n + d_0 - a_0 \Delta x f(v_0^n) \quad (25)$$

$$v_{N-1}^{n+1} = (a_{N-1} + c_{N-1}) v_{N-2}^n + b_{N-1} v_{N-1}^n + c_{N-1} \Delta x f(v_{N-1}^n) + d_{N-1} \quad (26)$$

1.4.2 Explicit Method

For the implicit method, it is quite a bit more complicated. On the RHS of 5, we can just substitute for v_{-1} as with the explicit method.

$$a_0^R v_{-1}^n + b_0^R v_0^n + c_0^R v_1^n + d_0 = a_0^R [v_1^n - \Delta x f(v_0^n)] + b_0^R v_0^n + c_0^R v_1^n + d_0 \quad (27)$$

For the LHS however, $f(v)$ needs to be evaluated at v_0^{n+1} , which isn't known. We approximate this by expanding $f(v)$ in a Taylor series, and only keeping the first two terms.

$$f(v_0^{n+1}) \approx f(v_0^n) + f'(v_0^n)(v_0^{n+1} - v_0^n) \quad (28)$$

Now the LHS of 5 can be written as

$$\begin{aligned} a_0^L v_{-1}^{n+1} + b_0^L v_0^{n+1} + c_0^L v_1^{n+1} &= a_0^L \left[v_1^{n+1} - \Delta x \left(f(v_0^n) + f'(v_0^n)(v_0^{n+1} - v_0^n) \right) \right] \\ &\quad + b_0^L v_0^{n+1} + c_0^L v_1^{n+1} \end{aligned} \quad (29)$$

Note that any terms that are constant (i.e. do not contain a v^{n+1}) must be moved over to the RHS, so after some rearranging,

$$LHS : \left[b_0^L - a_0^L \Delta x f'(v_0^n) \right] v_0^{n+1} + \left[c_0^L + a_0^L \right] v_1^{n+1} \quad (30)$$

$$\begin{aligned} RHS : &b_0^R v_0^n + c_0^R v_1^n + d_0 \\ &+ \left[-a_0^L \Delta x f'(v_0^n) v_0^n + a_0^R v_1^n - a_0^R \Delta x f(v_0^n) + a_0^L \Delta x f(v_0^n) \right] \end{aligned} \quad (31)$$

Comparing these to ??, we see that in fact they just contain ?? plus some extra terms. Therefore, in general, we can *assume* that we have a sink boundary condition when we create the representation for the first and last equations, and then add an arbitrary boundary condition on by adding on to the right terms. All the extra information we need is the boundary condition function and its derivative with respect to v .

Let

$$b_0'^L \equiv -a_0^L \Delta x f'(v_0^n) \quad (32)$$

$$c_0'^L \equiv a_0^L \quad (33)$$

$$b_0'^R \equiv -a_0^L \Delta x f'(v_0^n) \quad (34)$$

$$c_0'^R \equiv a_0^R \quad (35)$$

$$d_0' \equiv a_0^L \Delta x f(v_0^n) - a_0^R \Delta x f(v_0^n) \quad (36)$$

Then we can write the boundary equation as

$$\left(b_0^L + b_0'^L \right) v_0^{n+1} + \left(c_0^L + c_0'^L \right) v_1^{n+1} = \left(b_0^R + b_0'^R \right) v_0^n + \left(c_0^R + c_0'^R \right) v_1^n + d_0 + d_0' \quad (37)$$

For the other boundary, $i = N - 1$, equation 5 gives

$$v_N = v_{N-2} + \Delta x f(v_0). \quad (38)$$

Again, the boundary condition can be incorporated directly into the RHS, but a Taylor Series approximation must be used for the LHS. The left and right sides will look like this

$$\begin{aligned}
LHS : & a_{N-1}^L v_{N-2}^{n+1} + b_{N-1}^L v_{N-1}^{n+1} \\
& + \left[c_{N-1}^L v_{N-2}^{n+1} + c_{N-1}^L \Delta x f(v_{N-1}^n) + c_{N-1}^L \Delta x f'(v_{N-1}^n) (v_{N-1}^{n+1} - v_{N-1}^n) \right] \\
RHS : & a_{N-1}^R v_{N-2}^n + b_{N-1}^R v_{N-1}^n + d_{N-1} \\
& + \left[c_{N-1}^R v_{N-2}^n + c_{N-1}^R \Delta x f(v_{N-1}^n) \right]
\end{aligned}$$

and then we have to move the constant terms from the LHS to the RHS

$$\begin{aligned}
LHS : & a_{N-1}^L v_{N-2}^{n+1} + b_{N-1}^L v_{N-1}^{n+1} \\
& + \left[c_{N-1}^L v_{N-2}^{n+1} + c_{N-1}^L \Delta x f'(v_{N-1}^n) v_{N-1}^{n+1} \right] \tag{39}
\end{aligned}$$

$$\begin{aligned}
RHS : & a_{N-1}^R v_{N-2}^n + b_{N-1}^R v_{N-1}^n + d_{N-1} \\
& + \left[c_{N-1}^R v_{N-2}^n + c_{N-1}^R \Delta x f(v_{N-1}^n) - c_{N-1}^L \Delta x f(v_{N-1}^n) + c_{N-1}^L \Delta x f'(v_{N-1}^n) v_{N-1}^n \right] \tag{40}
\end{aligned}$$

Now, defining a set of prime constants again,

$$a_{N-1}'^L \equiv c_{N-1}^L \tag{41}$$

$$b_{N-1}'^L \equiv c_{N-1}^L \Delta x f'(v_0^n) \tag{42}$$

$$a_{N-1}'^R \equiv c_{N-1}^R \tag{43}$$

$$b_{N-1}'^R \equiv c_{N-1}^L \Delta x f'(v_0^n) \tag{44}$$

$$d_{N-1}' \equiv c_{N-1}^R \Delta x f(v_{N-1}^n) - c_{N-1}^L \Delta x f(v_{N-1}^n) \tag{45}$$

Then we can write the boundary equation as

$$\begin{aligned}
& (a_{N-1}^L + a_{N-1}'^L) v_{N-2}^{n+1} + (b_{N-1}^L + b_{N-1}'^L) v_{N-1}^{n+1} \\
& = (a_{N-1}^R + a_{N-1}'^R) v_{N-2}^n + (b_{N-1}^R + b_{N-1}'^R) v_{N-1}^n + d_{N-1} + d_{N-1}' \tag{46}
\end{aligned}$$

So, we now have a general, concise method for implementing any type of Neumann boundary condition. Note that, while in general the method relies on an approximation involving the Taylor Series expansion of the boundary condition

function, it gives the same equations as directly implementing a boundary condition that is linear in v . Meaning, the boundary condition used to model energy loss due surface convection,

$$\kappa \left. \frac{\partial v}{\partial x} \right|_{x=0} = h_e (v - v_\infty) \quad (47)$$

can be directly implemented without the use of a Taylor Series expansion, because there are no non-linear terms. However, doing so leads to the exact same equations as 30, 31, 39, and 40 with $f(v_i^n) = \frac{h_e}{\kappa} (v_i^n - v_\infty)$ and $f'(v_i^n) = \frac{h_e}{\kappa}$. The same is true for the insulating boundary conditions. Therefore, there is no reason to implement linear boundary conditions separatly, this general method will give the exact same results.

1.5 Time-Dependent Boundary Conditions

If the boundary condition is time dependent, for example if the ambient temperature is a function of time, then the boundary conditions will be

$$v(x_0) = f(t) \quad (48)$$

or

$$\left. \frac{\partial v}{\partial x} \right|_{x=\text{boundary}} = f(v, t) \quad (49)$$

, then the primed coefficients need to be updated. Any factors of f or f' that start out on the left hand side should be evaluated at the next timestep. So, for the sink boundary condition, we have

$$d'_0 = a^R_0 f(t) - a^L_0 f(t + \Delta t) \quad (50)$$

and

$$d'_{N-1} = c^R_{N-1} f(t) - c^L_{N-2} f(t + \Delta t) \quad (51)$$

For the heat flux boundary conditions we have

$$b'^L_0 \equiv -a^L_0 \Delta x f'(v_0^n, t + \Delta t) \quad (52)$$

$$c'^L_0 \equiv a^L_0 \quad (53)$$

$$b'^R_0 \equiv -a^L_0 \Delta x f'(v_0^n, t + \Delta t) \quad (54)$$

$$c'^R_0 \equiv a^R_0 \quad (55)$$

$$d'_0 \equiv a^L_0 \Delta x f(v_0^n, t + \Delta t) - a^R_0 \Delta x f(v_0^n, t) \quad (56)$$

and

$$a'^L_{N-1} \equiv c^L_{N-1} \quad (57)$$

$$b'^L_{N-1} \equiv c^L_{N-1} \Delta x f'(v_0^n, t + \Delta t) \quad (58)$$

$$a'^R_{N-1} \equiv c^R_{N-1} \quad (59)$$

$$b'^R_{N-1} \equiv c^L_{N-1} \Delta x f'(v_0^n, t + \Delta t) \quad (60)$$

$$d'_{N-1} \equiv c^R_{N-1} \Delta x f(v_{N-1}^n, t) - c^L_{N-1} \Delta x f(v_{N-1}^n, t + \Delta t) \quad (61)$$

If the boundary conditions are constant in time, these primed coefficients reduce to the same as before. So the only terms that must be evaluated for the current and next time time are the d' 's. In fact, all of the primed coefficients can be evaluated for the next time step *except* the d' 's.

1.6 Heat Flux Boundaries

For the heat equation, the heat flux at the boundary is usually specified, rather than the temperature derivative.

$$k \frac{dv}{dx} = f(x, t) \quad (62)$$

If the heat flux, $k \frac{dv}{dx}$ is positive, it means that thermal energy flows to the “left”. If it is negative, the thermal energy flows to the “right”. Because of this, there is a sign difference between the upper and lower boundaries from the point of view of energy leaving the system or entering the system. At the lower boundary, a positive heat flux corresponds to energy leaving the system as heat,

$$k \frac{dv}{dx} = f(x, t). \quad (63)$$

At the upper boundary, a negative heat flux corresponds to energy leaving the system as heat,

$$k \frac{dv}{dx} = -f(x, t). \quad (64)$$

If we adopt the convention that a positive function corresponds to heat entering the system, regardless of which boundary it is applied to, then we need to account for this sign difference in the derivation of our primed coefficients above. This leads to all references of f and f' being replaced with $-f$ and $-f'$ for the $i = 0$ primed coefficients.
